Use case UC2: Patient Consultation
Primary Actor: Healthcare professional
Stakeholder and Interests:

Healthcare professional:

- Wants quick and efficient access to valid patient clinical records,
- Wants a functional process to record clinical information such as observations, diagnoses, treatment recommendations, and follow-up requirements,
- Wants to seamlessly issue prescriptions for one or more medications and follow-up appointments when necessary.

Patient:

- Wants to receive appropriate medical treatment and accurate records,
- Wants to ensure their confidentiality

Clinic:

- Wants consultation event to be tracked (start/end) and detailed with logs
- Wants accurate medical records entries by the health professionals,
- Wants protection of patient confidentiality.

Preconditions:

- Healthcare professional is authenticated and has access to the patient records
- The patient has an existing record in the database
- The patient's arrival has been registered by the clinic

Success Guarantee (Postconditions):

- The consultation has been successfully recorded in the system
- Patient record has been successfully updated
- Prescriptions have been issued if needed
- Follow-up appointments have been associated with the consultation

Main success scenario (or basic flow):

1. The Patient enters the consultation room, and the healthcare professional opens the patient's record.
2. The System displays the patient's record details (history) and begins the consultation session as the healthcare professional opens the record.
3. The Healthcare Professional records clinical information
4. If necessary, the Healthcare Professional issues a prescription and/or requests a follow-up appointment
5. The System records the follow-up request and the prescription and links them to the consultation.
6. The system records the changes in the consultation, and the System updates the patient's clinical record.
7. The Healthcare Professional ends the consultation.
8. The System saves the consultation and links it with the Patient and the Healthcare Professional, and the System records the end time in the consultation log.

Failure scenario (alternative flow):

3a. The Healthcare Professional tries to record clinical information without filling critical fields. The System notifies the Healthcare Professional and doesn't let them continue until those fields are filled.

Special Requirements:

- Patient details are formatted in a readable table layout in the terminal
- System flags should appear using formatted red text in the terminal
- The CLI session ends when it sits inactive for more than 10 minutes

Technology and Data Variations List:

- Healthcare Professional credentials, clinical information, prescriptions, follow-up requests are inputted through the command line.

Open Issues:

- What are the laws regarding post-editing of consultations?
- What are the confidentiality rules and the scope allocated to each healthcare professional regarding patient details?
